

The detected pixel agrees with the arm. The depth along that pixel's ray does not.

At the contact frame, over 58 contacts in 8 venues. The ray is the tracker's raw detection; the body never sees a shuttle.

(a) in the plane through the camera centre and the wrist

where the reconstruction puts the shuttle along the ray:
IQR -1.11 to $+1.65$ m, median bias $+0.21$ m

court plane — the body's depth is pinned here, by its ankles

(b) the control: the minimum is exactly at contact

A wrist that merely happened to lie near the shuttle's sight-line would not dip at frame 0. This is what rules out a misidentified striker.
